---

There are NO SAFE LEVELS OF GLYPHOSATE. PERIOD. The entire model for determining whether or not glyphosate is a carcinogen is based on the mistaken method of looking at a single chemical at relatively acute levels.

That testing model must be replaced with a more real life model of the effects of sub-acute, low-level exposure over long periods of time (preferably decades) in combination with exposure to other potentially activating chemicals and heavy metals common to modern day life AND their effects on humans as small as a fetus, not just full grown.

BAN GLYPHOSATE. There has not been enough comprehensive testing yet done.
